

Genetic Algorithm Requirements

- No hard-coding
- Function: $Ratio = (Portfolio\ return - risk\ free\ returns) \div portfolio\ volatility$
- We need a genetic algorithm that will evaluate the ROI from our set of stocks, which will be provided in a JSON file.
- In order to evaluate the model, we will compare the generated portfolios against existing portfolios, randomly assigned portfolios, and a simple division of portfolios. The dataset that will be used is 5-50 stocks selected from freely available financial datasets such as Yahoo Finance, Google Finance, or the S&P 500.
- Create a first parent by dividing the money evenly per stock, and then use that to start the genetic algorithm.
